The International Federation for Medical and Biological Engineering, IFMBE, is a federation of national and transnational organizations representing internationally the interests of medical and biological engineering and sciences. The IFMBE is a non-profit organization fostering the creation, dissemination and application of medical and biological engineering knowledge and the management of technology for improved health and quality of life. Its activities include participation in the formulation of public policy and the dissemination of information through publications and forums. Within the field of medical, clinical, and biological engineering, IFMBE's aims are to encourage research and the application of knowledge, and to disseminate information and promote collaboration. The objectives of the IFMBE are scientific, technological, literary, and educational.

The IFMBE is a WHO accredited NGO covering the full range of biomedical and clinical engineering, healthcare, healthcare technology and management. It is representing through its 60 member societies some 120.000 professionals involved in the various issues of improved health and health care delivery.

#### IFMBE Officers

President: James Goh, Vice-President: Shankhar M. Krishnan

Past President: Ratko Magjarevic

Treasurer: Marc Nyssen, Secretary-General: Kang Ping LIN

## Preface

This book presents the proceedings of the IUPESM World Congress on Biomedical Engineering and Medical Physics, a triennially organized joint meeting of medical physicists, biomedical engineers, and adjoining healthcare professionals. Besides the purely scientific and technological topics, the 2018 Congress will also focus on other aspects of professional involvement in health care, such as education and training, accreditation and certification, health technology assessment, and patient safety. The IUPESM meeting is an important forum for medical physicists and biomedical engineers in medicine and healthcare to learn and share knowledge, and to discuss the latest research outcomes and technological advancements as well as new ideas in both medical physics and biomedical engineering field.

Biomedical engineering and medical physics represent challenging and rapidly growing areas. Building on the success of the previous World Congresses, the aim of the World Congress 2018 is to continue in bringing together scientists, researchers, and practitioners from different disciplines, namely from mathematics, computer science, bioinformatics, biomedical engineering, medical physics, medicine, biology, and different fields of life sciences, so that they can present and discuss their research results. We hope that the World Congress 2018 will serve as a platform for fruitful discussions between all attendees, where participants can exchange their recent results, identify future directions and challenges, initiate possible collaborative research, and develop common languages for solving problems in the realm of biomedical engineering and medical physics.

Following a thorough peer-reviewed process, we have finally selected 498 papers. The Scientific Committee would like to thank the reviewers for their excellent job. The articles can be found in the proceedings and are divided into the main tracks and special sessions. The papers show how broad the spectrum of topics in biomedical engineering and medical physics is.

The editors would like to thank all the participants for their high-quality contributions and Springer for publishing the proceedings of the World Congress.

# Organizing Committees

## **Congress Coordinating Committee**

### **Chair**

Kin Yin Cheung, Chair, IOMP, Hong Kong

### **Members**

Howell Round, IOMP, New Zealand

Slavik Tabakov, IOMP, UK

Virginia Tsapaki, IOMP, Greece

James Goh, IFMBE, Singapore

Kang Ping Lin, IFMBE, Chinese Taipei

Herb Voigt, co-opted, IFMBE, USA †

Monique Frize, co-opted, IFMBE, Canada

## **Congress Organizing Committee**

### **Co-chairs**

Jaromir Cmiral, Czech Republic, BME

Libor Judas, Czech Republic, MedPhys

### **Secretaries**

Frantisek Lopot, Czech Republic, BME

Karel Nechvil, Czech Republic, MedPhys

### **Members**

#### **Financial Committee Co-chairs**

Martin Mayer, Czech Republic, BME

Vít Richter, Czech Republic, MedPhys

#### **Scientific Committee Co-chairs**

Lenka Lhotska, Czech Republic, BME

Lucie Sukupova, Czech Republic, MedPhys

#### **Publicity Committee Chair**

Martina Novakova, Czech Republic, BME, MedPhys

#### **Education Committee Co-chairs**

Jiri Hozman, Czech Republic, BME

Irena Koniarova, Czech Republic, MedPhys

## Financial Committee

### Co-chairs

Martin Mayer, Czech Republic, BME  
Vit Richter, Czech Republic, MedPhys

### Members

Jan Hanousek, Czech Republic, BME  
Anchali Krisanachinda, IOMP  
Mark Nyssen, IUPESM, IFMBE  
Vaclav Poljak, Czech Republic, MedPhys

## Scientific Committee

### Co-chairs

Geofrey Ibbott, IOMP  
Lenka Lhotska, Czech Republic, BME  
Igor Lackovic, IFMBE  
Lucie Sukupova, Czech Republic, MedPhys

### Members

## About IFMBE

The International Federation for Medical and Biological Engineering (IFMBE) is primarily a federation of national and transnational societies. These professional organizations represent interests in medical and biological engineering. IFMBE is also a non-governmental organization (NGO) for the United Nations and the World Health Organization (WHO), where we are uniquely positioned to influence the delivery of health care to the world through biomedical and clinical engineering.

The IFMBE's objectives are scientific and technological as well as educational and literary. Within the field of medical, biological, and clinical engineering, IFMBE's aims are to encourage research and application of knowledge and to disseminate information and promote collaboration. The ways in which we disseminate information include the following: organizing World Congresses and Regional Conferences, publishing our flagship journal *Medical and Biological Engineering and Computing* (MBEC), our Web-based newsletter—IFMBE News, our Congress and Conference Proceedings, and books. The ways in which we promote collaborations are through networking programs, workshops, and partnerships with other professional groups, e.g., Engineering World Health.

### *Mission*

The mission of IFMBE is to encourage, support, represent, and unify the worldwide medical and biological engineering community in order to promote health and quality of life through the advancement of research, development, application, and management of technology.

### *Objectives*

The objectives of the International Federation for Medical and Biological Engineering shall be scientific, technological, literary, and educational. Within the field of medical, clinical, and biological engineering, its aims shall be to encourage research and the application of knowledge and to disseminate information and promote collaboration.

In pursuit of these aims, the Federation may, in relation to its specific field of interest, engage in any of the following activities: sponsorship of national and international meetings, publication of official journals, cooperation with other societies and organizations, appointment of commissions on special problems, awarding of prizes and distinctions, establishment of professional standards and ethics within the field, or in any other activities which in the opinion of the General Assembly or the Administrative Council would further the cause of medical, clinical, or biological engineering. It may promote the formation of regional, national, international, or specialized societies, groups or boards, the coordination of bibliographic or informational services, and the improvement of standards in terminology, equipment, methods and safety practices, and the delivery of health care.

In general, the Federation shall work to promote improved communication and understanding in the world community of engineering, medicine, and biology.

# Analysis of Electroencephalographic Dynamic Functional Connectivity in Alzheimer's Disease

Pablo Núñez<sup>✉</sup>, Jesús Poza<sup>✉</sup>, Carlos Gómez<sup>✉</sup>, Saúl J. Ruiz-Gómez<sup>✉</sup>, Víctor Rodríguez-González, Miguel Ángel Tola-Arribas, Mónica Cano, and Roberto Hornero<sup>✉</sup>

## Abstract

The aim of this study was to characterize the dynamic functional connectivity of resting-state electroencephalographic (EEG) activity in Alzheimer's disease (AD). The magnitude squared coherence (*MSCOH*) of 50 patients with dementia due to AD and 28 cognitively healthy controls was computed. *MSCOH* was estimated in epochs of 60 s subdivided in overlapping windows of different lengths (1, 2, 3, 5 and 10 s; 50% overlap). The effect of epoch length was tested on *MSCOH* and it was found that *MSCOH* stabilized at a window length of 3 s. We tested whether the *MSCOH* fluctuations observed reflected actual changes in functional connectivity by means of surrogate data testing, with the standard deviation of *MSCOH* chosen as the test statistic. The results showed that the variability of the measure could be due to dynamic functional connectivity. Furthermore, a significant reduction in the dynamic *MSCOH* connectivity of AD patients compared to controls was found in the delta (0–4 Hz) and beta-1 (13–30 Hz) bands. This indicated that AD patients show lesser variation in neural connectivity during resting state. Finally, a correlation between relative power and standard deviation was found, suggesting that an increase/peak in power spectrum could be a pre-requisite for dynamic functional connectivity in a specific frequency band.

## Keywords

Alzheimer's disease • Dynamic functional connectivity  
Electroencephalogram • Neural dynamics  
Coherence • Relative power

## 1 Introduction

Alzheimer's disease (AD) neurodegeneration has an effect on the temporally coordinated brain networks, which underlie cognitive functions. These networks become more abnormal with the progression of AD, as alterations in the processing and transmission of information begin to appear [1]. The aberrant brain networks associated to AD can be reflected in the alterations of the synchronization patterns and brain connectivity observed in resting-state electroencephalographic (EEG) recordings [1].

The majority of studies focusing on brain synchronization and connectivity during resting state assume that functional connectivity (FC) remains temporally stationary. However, it is important to take the spontaneous fluctuations of brain activity into account, as it has been suggested that resting-state activity is not stationary [2]. Thus, the quantification of dynamic changes in FC metrics could provide relevant information regarding the stability of brain networks [3].

Most dynamic functional connectivity (dFC) studies in the literature have been performed with functional magnetic resonance imaging (fMRI) recordings [3]. Therefore, the study of dFC on electroencephalographic (EEG) recordings is of great interest. In the specific case of AD, only a small number of studies have addressed the characterization of FC variability patterns [3].

This paper presents a novel methodology, aimed at obtaining a first approximation to the dynamics of FC in AD. Specifically, this study addresses the following research questions: (i) what epoch length is needed to obtain stable connectivity measures?; (ii) can dFC be found in AD

patients and healthy controls?; (iii) do dFC patterns differ between both groups?

## 2 Materials

### 2.1 Subjects

A population of 28 healthy control subjects (C) and 50 patients with AD was analyzed. The subjects were matched by age. Patients were diagnosed according to the criteria of the National Institute on Aging and Alzheimer's Association (NIA-AA) [4]. The controls were elderly people without cognitive impairment, or history of neurological or psychiatric diseases. None of the participants took medications that could influence EEG records.

The socio-demographic characteristics of each group are specified in Table 1. All participants and caregivers were informed about the research and study protocol and gave their written and informed consent. The Ethical Committee of the "Río Hortega" University Hospital (Valladolid, Spain) approved the study according to the Code of Ethics of the World Medical Association (Declaration of Helsinki).

### 2.2 Electroencephalographic Recordings

EEG signals were recorded using a 19-channel EEG system (XLTEK<sup>®</sup>, Natus Medical) at the Department of Clinical Neurophysiology of the "Río Hortega" University Hospital. EEG activity was acquired from Fp1, Fp2, Fz, F3, F4, F7, F8, Cz, C3, C4, T3, T4, T5, T6, Pz, P3, P4, O1 y O2, at a sampling frequency of 200 Hz. Subjects were asked to remain with eyes closed, awake, and still during EEG acquisition. Five minutes of EEG activity were recorded for each subject. After a preliminary independent component analysis to remove artifacted components, the EEG recordings were then preprocessed in three steps: (i) filtering using a notch filter (50 Hz) and a Hamming window bandpass filter ([1 70] Hz); (ii) segmentation into 5 s epochs; and (iii) visual rejection of artifacts, selecting the first 60 consecutive seconds without artifacts for each subject.

## 3 Methods

### 3.1 Estimation of Variability

Coherency (COH) is a measure that analyzes the consistency between the EEG activity of different pairs of electrodes in order to characterize the connectivity between brain regions. COH is the standardized cross-spectrum of signals  $X$  and  $Y$  across trials, divided by the product of their power spectrum. Magnitude squared COH (MSCOH) combines sensitivity to both phase and magnitude synchrony and is defined as [5]:

$$MSCOH_{xy}(f, t) = |COH_{xy}(f, t)|^2 = \frac{|S_{XY}(f, t)|^2}{P_X(f, t)P_Y(f, t)} \quad (1)$$

where  $S_{XY}$  is the cross-spectrum of  $X$  and  $Y$ , and  $P_X$  and  $P_Y$  are the power spectral density (PSD) of  $X$  and  $Y$ , respectively. The relative power (RP) was computed from the PSD in the conventional frequency bands: delta ( $\delta$ , 1–4 Hz), theta ( $\theta$ , 4–8 Hz), alpha ( $\alpha$ , 8–13 Hz), beta-1 ( $\beta_1$ , 13–19 Hz), beta-2 ( $\beta_2$ , 19–30 Hz) and gamma ( $\gamma$ , 30–70 Hz).

### 3.2 Protocol

In order to study the dynamic properties of functional connectivity coupling patterns, MSCOH was computed between each pair of electrodes over the 60 s epochs by means of sliding windows with 50% overlap. Afterwards, the mean value of MSCOH ( $\mu_{MSCOH}$ ) and the standard deviation ( $\kappa_{MSCOH}$ ) were obtained.  $\kappa_{MSCOH}$  was used as the test statistic in order to detect the existence of dFC [6]. The connectivity matrixes for each frequency band were grouped into five regions (frontal, left-temporal, right-temporal, central and parieto-occipital) and inter-regional and intra-regional  $\mu_{MSCOH}$  and  $\kappa_{MSCOH}$  values were averaged among the electrodes within each region pair. After this procedure, the connectivity matrix was reduced to a  $5 \times 5$  size (5 regions). All subsequent analyses were performed on these matrixes. This procedure was performed on windows of 1, 2, 3, 5 and 10 s, in the aforementioned 6 conventional frequency bands.

**Table 1** Socio-demographic and clinical data. Mean values  $\pm$  standard deviation. A: primary education or below; B: secondary education or above; MMSE: Mini-Mental State Examination

### 3.3 Statistical Analysis

Shapiro-Wilk and Levene tests showed that  $\mu_{MSCOH}$  and  $\kappa_{MSCOH}$  values did not meet parametric test conditions. Then, the Mann-Whitney  $U$ -test was used to evaluate the differences between groups across each frequency band and region. An FDR correction was performed in order to correct for multiple comparisons. Furthermore, a Spearman correlation analysis was performed between the RP values and the average  $\kappa_{MSCOH}$  values of each channel.

### 3.4 Analysis of Window Stability

The Friedman test was used on the  $\mu_{MSCOH}$  values to detect the effects of window length on the MSCOH measures. In case the Friedman test showed a significant effect, Dunn's multiple comparison test was applied to determine the window in which the MSCOH measurements became stable, defined as the shortest window length that does not show significant differences with longer window sizes [7].

### 3.5 Detection of Dynamic Functional Connectivity

It is important to take into account the fact that the mere presence of fluctuations in connectivity measures is not

sufficient proof of the existence of dFC. Due to the noisy nature of the recordings, the fact that the observed connectivity values are estimates of the true FC values cannot be ignored [6]. Therefore, in order to determine whether the observed fluctuations reflect real FC changes, an adequate statistical test must be carried out [6]. We followed the statistical test described by Prichard and Theiler [8], which has been previously used by Hindriks et al. [6]. In our case, 1000 surrogate versions of each EEG segment were constructed from the original signals.

## 4 Results and Discussion

First, we determined the window size in which the MSCOH measurements became stable. It was found that for both groups this size was 3 s. All further tests were thus performed on values obtained with a 3 s sliding window. We then assessed whether the  $\kappa_{MSCOH}$  values were statistically significant [6]. For each, inter-regional and intra-regional pair we performed an FDR correction on the  $p$ -values associated with the  $z$ -scores of all the connections within each pair. After this, we determined that a regional pair had dFC if at least one of the connections within it had a statistically significant  $\kappa_{MSCOH}$  value after the FDR correction.

Figure 1a shows the number of subjects that showed statistically significant  $\mu_{MSCOH}$  in each regional pair. The beta-1 band showed the highest number of regional pairs

**Fig. 1** MSCOH dFC analysis for a 3-s sliding window. **a** Percentage of subjects that showed statistically significant  $\mu_{MSCOH}$  in each regional pair for each group. **b** Statistically significant  $p$ -values for the  $\kappa_{MSCOH}$  comparisons between groups. Red values indicate greater  $\kappa_{MSCOH}$  for C than AD patients, while blue values indicate greater  $\kappa_{MSCOH}$  for AD

patients than C. **c** Correlation between RP values and  $\kappa_{MSCOH}$  for each group. Only the bands with significant between-group differences are shown. Correspondence with regions F: frontal, C: central, LT: left-temporal, RT: right-temporal, PO: parieto-occipital (Color figure online)

with dFC, especially for controls, nearing 50% of subjects in some cases. The statistical differences in  $\mu_{MSCOH}$  between groups are also shown in Fig. 1b. The most statistically significant differences were located in the beta-1 band, especially in the connections between the right-temporal region and the remaining ones. These results are consistent with previous findings that support the role of the right hemisphere in brain disconnection related to AD [9]. Less statistically significant differences were also found in the delta band. Controls showed more variation in connectivity than AD patients, which is in agreement with other studies that found a loss of irregularity and variability in AD neural activity [9].

The correlation analysis between RP and the average  $\kappa_{MSCOH}$  values of each EEG channel in each band, displayed in Fig. 1c, showed statistically significant positive correlation in the delta, theta and alpha band for most regions in controls. AD patients, on the other hand, showed weaker positive correlation in the beta-1 band as well, suggesting that spectral power is a pre-requisite for dFC.

This study has some limitations. Firstly, more controls should be included in the database in order to balance the number of AD patients and controls. Furthermore, a third group of mild cognitive impairment (MCI) patients should be included in future studies, given its importance as a prodromal form of AD [9].

## 5 Conclusion

The results suggest that MSCOH variability could be due to dFC. Moreover, AD patients show lesser variation in neural connectivity than controls, which suggests a loss of variability in AD. Finally, the correlation between relative power and  $\kappa_{MSCOH}$  hints that a peak in power spectrum in a frequency band could be a pre-requisite for dFC.

**Acknowledgements** This study has been partially funded by projects TEC2014-53196-R of ‘Ministerio de Economía y Competitividad’ and FEDER, the project ‘Análisis y correlación entre el genoma completo y la actividad cerebral para la ayuda en el diagnóstico de la enfermedad de Alzheimer’ (Inter-regional cooperation program VA Spain-Portugal POCTEP 2014–2020) of the European Commission and FEDER, and project VA037U16 of the ‘Junta de Castilla y León and FEDER.
